

Insulating glass units (IGUs) are used in windows, doors, and skylights to provide thermal and acoustic insulation. They consist of two or more glass panes held together by a spacer and sealed with a gas or air.

Insulating glass units (IGUs) are used in windows, doors, and skylights to provide thermal and acoustic insulation.

Insulating glass units (IGUs) are used in windows, doors, and skylights to provide thermal and acoustic insulation. They consist of two or more glass panes held together by a spacer and sealed with a gas or air. The spacer is typically made of aluminum or stainless steel and is filled with a gas or air. The gas or air is typically argon or krypton, which has a lower thermal conductivity than air. This helps to reduce heat loss through the window. IGUs also provide acoustic insulation by reducing the transmission of sound through the window. They are also used in skylights to provide thermal and acoustic insulation. IGUs are used in a wide range of applications, from residential windows to commercial buildings and industrial facilities. They are a key component of energy-efficient building design.

Insulating glass units (IGUs) are used in windows, doors, and skylights to provide thermal and acoustic insulation.

1. Insulating glass units (IGUs) are used in windows, doors, and skylights to provide thermal and acoustic insulation. They consist of two or more glass panes held together by a spacer and sealed with a gas or air. The spacer is typically made of aluminum or stainless steel and is filled with a gas or air. The gas or air is typically argon or krypton, which has a lower thermal conductivity than air. This helps to reduce heat loss through the window. IGUs also provide acoustic insulation by reducing the transmission of sound through the window. They are also used in skylights to provide thermal and acoustic insulation.
